Description

Description

It is an evergreen succulent plant with short leaves arranged in rosettes 6–12 cm in diameter. The succulent leaves are tapered ("*attenuata*" means "tapering") and have bands of white tubercles on them. The species subdivides and offsets readily; in the wild it forms large

clumps. It is popular as a house plant, due to its resistance to drought and general hardiness.

It is frequently confused with the rarer *Haworthiopsis fasciata*, to which it looks very similar. However *Haworthiopsis attenuata* can easily be distinguished by its white tubercles, which occur on both upper and lower sides of its leaves (*H. fasciata* has tubercles only on the underside, with a smooth upper surface of its leaves). A fundamental distinction is that *H. attenuata*'s leaves are not fibrous. In addition, the leaves of *H.attenuata* are often (though not always) longer, thinner, and more splayed out.

Care

Like most succulents, *Haworthiopsis attenuata* prefer soil with adequate drainage, such as cactus mix or fast-draining potting soil mixed with sand. They like bright light, but too much direct sunlight can cause leaves to turn white or yellow. The plants should be watered evenly and generously during the summer, allowing the soil to dry out between watering. In the winter, they can be watered as infrequently as once every two weeks.

Their flowers appear in November and December.
